Howard D. Sullivan, Deputy

Winter Wheat.-The Colorado crop of winter wheat held about steady in condition during the month of April, due to good rains during the forepart of the month in most districts except the east-central and southeast. The preliminary estimates of Way 1 forecast a crop of 13,741,000 bushels. This estimate is based upon the May 1 condition of 65 per cent representing about 13 bushels per acre for 1,057,000 acres left for harvest from a sowing last fall of 1,578,000 acres. The abandonment, or the acreage that was sown last fall and will be plowed up and put into other crops or otherwise considered unfit for harvest as winter wheat, amounted to 33 per cent of the area sown. compared with 20 per cent last year and 9.6 per cent for the past five years. The crop harvested last year amounted to 16,406,000 bushels, an average yield of 13 bushels per acre on 1.262,000 acres. In 1919, the average yield was only 13.2 bushels per acre. Only under exceptionally favorable conditions during the remainder of the season can the yield exceed 10 or 11 bushels per acre for the acreage remaining for harvest. Approximately 93 per cent of the winter wheat of Colorado is grown upon non-irrigated land. The non-irrigated farming sections in the northern and northeastern parts have fair surface moisture conditions for the present, but the subsoil is considered deficient. The cast-central and especially the southeastern counties of the state have been and are still suffering from long continued drouth, and more or less wind and other winter In nearly all eastern slope sections early sown wheat suffiered exxtremely. Much of it sprouted but lacked moisture to bring it up and sustain good growth. Of the late sown fall wheat much of it came up this spring and is unseasonably small. Winter wheat is generally in better condition in the western counties and upon farms under irrigation where only about the usual abandonment occurred.

The United States winter wheat crop improved 4.9 points in condition during the month of April and was rated on May 1, at 80.1, compared with 75.2 on April 1, 83.5 on May 1, 1922, and 87.5, the average for the past 10 years on May 1. The condition at this time indicates an average yield of approximately 14.6 bushels per acre, assuming average variations to prevail hereafter. The per cent of abandonment was 14.3, compared with 9.8, the 10-year average. The area left for harvest was estimated at 39,750.-600 acres, compared with 42,127,000 acres harvested last year. The production is placed at 578,287,000 bushels, or 1.3 per cent less than in 1922, 3.7 per cent less than in 1921, 5.3 per cent less than in 1920, and 1.6 per cent less than the 589,854,000 bushel average of the past ten years.

For other and more complete state and United States figures for winter wheat, rye, hay, pastures, plowing, spring planting and livestock, see table on page 4.

Rye.—The condition of the 78,000 acres of fall rye of the state left for harvest as grain is 75 per cent of normal, compared with 85 last year and 91 the ten-year average. This low condition is also due to the generally adverse drouth period that effected wheat. The index of condition justifies a forecast of about 10.5 bushels per acre, or a grain production of fall rye of \$19,000 bushels. In addition to the fall rye there will also

probably be some 13,000 acres more or less of spring rye cut for grain, which will add to the total rye production of the state. Besides the rye cut for grain last year, there were about 35,000 acres cut green for hay and 29,000 acres pastured or abandoned. In 1922 about 60 per cent of the rye acreage was harvested for grain. It is likely that similar conditions will prevail in this respect this year. Practically the entire acreage of rye in this state is grown upon non-irrigated land. It is a valuable and quite sure crop either for hay, pasture or grain.

Hay.—Based upon a condition of 90 per cent of normal, the hay crop of the state is placed at 2,580,000 tons, compared with the final estimate of 2,709,000 tons last year. According to preliminary reports there is a decrease of about 5 per cent in the acreage devoted to tame hay this year with practically no change in wild hay. The acreage of tame hay is placed at 1,178,000 acres and wild hay at 366,000 acres. There is considerable variation in the acreage devoted to tame hay on account of the grains cut green, millet and other tame grasses that make up the area devoted to this crop. On May 1, about 8 per cent of last year's hay crop or 217,000 tons, remained on the farms of the state, compared with 17 per cent or 495,000 tons of the 1921 crop on hand a year ago, and 785,000 tons (25 per cent) of the 1920 crop, on hand May 1, 1921. This is the lowest hay reserve in recent years, except in 1919 when there was only 6 per cent. Even though the winter was generally open and mild, in many localities a long feeding period was required. Due to the drouth of last season and consequent shortage of pastures, feed generally became scarce and high priced.

Livestock.—Generally the stock on the farms and ranges of Colorado reached May 1 in fair to good condition, slightly below the 10-year average. Due to favorable weather conditions the mortality of livestock for the year ending May 1, as shown by the losses per thousand head, were a little less than last year, and quite a little under the ten-year average figures. All livestock has been healthy though frequently in thin condition.

Dry Beans.—Replies to special inquiries on intentions to plant indicate that, unless the farmers of the state materially revise their plans, the bean acreage in Colorado, this year, will be about 32 per cent greater than that of last year, when approximately 108,000 acres were planted and 81,000 acres were harvested. This would mean from 142,000 to 150,000 acres will be planted this year. The results of this bean inquiry are issued that growers may have information regarding the trend in this crop.

Potatoes.—Replies to the same kind of an inquiry on the intentions of farmers to plant potatoes in Colorado this year, indicate that the acreage to be planted will be about 18 per cent less than that of last year, which would mean that approximately 125,000 acres will be planted, or about 117,000 acres for harvest, compared with 152,000 planted last year, from which about 142,000 acres were harvested. The reports show an irrigated planting of about 81 per cent, or 102,000 acres, and the non-irrigated planting compared to last year of 87 per cent, or about 23,000 acres. This inquiry on prospective potato planting was made on April 1 and also on May 1, and the results reported at this time, in order that farmers throughout the state may have some knowledge of the trend in the potato business, and if they so desire, may increase or decrease their plantings accordingly.

Agricultural Outlook.—The soil condition for Colorado on May 1, as indicated by the average reports, held just steady during April, and was 90 per cent as compared with 95 per cent on May 1 last year, 102 per cent May 1, 1921, 110 per cent on May 1, 1920. Except in the east-central and southeastern districts present surface soil conditions are favorable. There is generally a lack of reserve moisture in the sub-soil over most of the plains sections. Timely and ample rains will be required to mature satisfactory crops, even in the sections where moisture is now fairly good. According to the weather bureau, the snow supply in the higher elevations is well above normal for this time of year, and promises fairly good late supplies for the irrigated sections, while the snow is already pretty well gone from the lower elevation water sheds. Reservoirs are generally well filled.

SUPPLEMENT TO COLORADO CROP BULLETIN NO. 46

^{&#}x27;Acreage and production of beets are credited, as in former reports, to the State in which the beets were made into sugar. For preliminary report of acreage and beet tonnage by States where grown, see Weather, Crops and Markets for December 23, 1922, page 572.

1922 figures are subject to revision, after final payments for beets have been determined.

Percentage of sucrose actually extracted by factories, based upon the weight of beets as worked (sliced). Compared with beets actually delivered (paid for) the sugar production of the United States in 1920 equaled 12.76 per cent of the beets paid for; in 1921, 13.11 per cent:

Based upon weight of beets immediately after slicing, except possibly in the case of a very few factories.

Percentage of sucrose (pure sugar) in the total soluble solids of the beets.

Sincluding beets and sugar from 1,500 acres in Canada in 1920; 1.500 acres in 1921; and 1.370 acres in 1922.

SUMMARY OF MAY 1, 1923, CROP AND LIVESTOCK REPORT FOR COLORADO AND THE UNITED STATES
