Hepatitis C in Colorado **2011** Surveillance Report

Cases of Acute and Chronic Hepatitis C in Colorado

Note: This report is published by the Viral Hepatitis Program (VHP), Disease Control and Environmental Epidemiology Division, Colorado Department of Public Health and Environment, Denver Colorado. Data are presented for acute and chronic hepatitis C cases newly reported to CDPHE in 2011

Colorado Department of Public Health and Environment

July 2012

Hepatitis C

Hepatitis C is the most common chronic blood borne infection in the United States. The severity and duration of Hepatitis C can range from mild symptoms lasting a few weeks to a serious lifelong illness, leading to cirrhosis and/or cancer of the liver. Data from the National Health and Nutrition Examination Survey conducted from indicate that between 2.7 and 3.9 million people in the United States are living with the hepatitis C virus (HCV). In Colorado, it is estimated that more than 70,000 residents have ever been infected with hepatitis C. Hepatitis C infections can be either "acute" or "chronic."

Viral hepatitis surveillance in Colorado is primarily based on laboratory reporting of serologic results. Laboratory-based reporting enables the identification of asymptomatic persons infected by the virus as well as those displaying symptoms. In Colorado, the Board of Health requires physicians and other health care providers to report suspected cases of acute hepatitis C within 7 days, and laboratories to report positive HCV serologic tests (including positive serum antibody titers with signal-to-cutoff ratios or more specific tests) within 7 days. Upon receipt of these reports, either electronically, by fax, or via another reporting system, the Viral Hepatitis Program (VHP) uses established case definitions to assign the appropriate diagnosis and case status for each patient.

Acute Hepatitis C

Acute hepatitis C is the first stage of hepatitis C infection and may be identified two weeks to six months after the exposure to the virus. Many people with hepatitis C do not have symptoms and do not know they are infected. If symptoms occur, they may include fever, fatigue, loss of appetite, nausea, vomiting, abdominal pain, dark urine, gray-colored stools, joint pain, and jaundice. Abnormal liver function tests are one of the most characteristic features.

Chronic Hepatitis C

Up to 85% of persons infected with hepatitis C, develop chronic infection. Chronic liver disease or liver cancer develops in approximately 15 -25% of people infected with the hepatitis C virus for 20 years or longer. When symptoms appear, they are often a sign of advance liver disease and may include the same symptoms as an acute infection.

Summary of Surveillance

If a variable is reported as missing, the information was not located by the disease investigators. If the variable is reported as unknown, then the investigator asked the question or located the information in a report and it was marked unknown. For example, a case investigator reviewed a medical record for a case and found a question related to race that was not marked. In that case, the variable was "missing". If a person did not know whether or not their household contacts had hepatitis C, they would respond "don't know" or "unknown".

Gender

In 2011, a total of 36 acute cases of hepatitis C were reported in Colorado. Of these, men and women each had eighteen reported cases of acute hepatitis infection. For chronic HCV infections, 64% of the total 3070 reported cases were among men (n=1961), as compared to 1,104 (36%) in women.

Age

Persons 30-39 years of age had the highest number of reported acute cases (n=12; 33%). For chronic infections, persons 50-59 years of age had the highest number of reported cases (n=1055; 34%). These reports support recent recommendations by the U.S. Centers for Disease Control and Prevention (CDC). The recommendation states that "Adults born during 1945-1965 should receive one-time testing for HCV without prior ascertainment of HCV risk"

Race/Ethnicity

Data on race and ethnicity was missing, unknown, or reported as other for almost half of the reported cases of chronic HCV (n=1471; 72%). Among the reported cases that included race, White non-Hispanics also had the highest number of chronic cases (n=1061; 35%). Rates per 100,000 were done using the 2011 estimates from the US Census Bureau, Population Division.²

Risk Factors

Risk factor data was added to the 2011 statistics. These data include: injection drug use (IDU), household contact, sex contact, men who have sex with men (MSM), born in endemic country, and perinatal. These data were obtained through patient interviews, medical record reviews, or information provided by a physician, hospital, or other healthcare provider. The VHP collected risk factor information on 31 (86%) acute HCV cases and 1017 (33%) chronic cases.

County Distribution

Acute hepatitis C was reported in 14 of the 64 Colorado counties. Chronic hepatitis C was reported in 61 of the 64 Colorado counties. Sixty-six percent of cases were reported from counties along Colorado's front range (Adams, Arapahoe, Boulder, Denver, El Paso, Jefferson, Larimer, Pueblo, and Weld.) Outside of Denver, rural and frontier counties (rural areas sparsely populated that are isolated from population centers and services), had the highest rates of reported chronic cases. However, this is based on small numbers of cases reported, and five rural and frontier counties did not report a case. Incarcerated HCV chronic cases are counted in the "Unspecified" section under Colorado Department of Corrections (CDOC).

Figure 1 map shows the rate distribution of hepatitis C per 100,000 county populations in Colorado. The rate is calculated using the 2011 estimated population figures from the Colorado Division of Local Government, Demography section.³

Reported Hepatitis C Cases Colorado, 2011 Colorado Electronic Disease Reporting System (CEDRS)

The rate is calculated using the Estimated 2011 Census figures from the Colorado Division of Local Government, Demography section. Rates calculated for counties with a small number of reported cases should be interpreted with caution.
