## **WATER LEVELS IN THE DENVER BASIN BEDROCK AQUIFERS**

**2008**

This report contains basic data concerning the depth to ground water and elevation of the occurrence of ground water in the four bedrock aquifers of the Denver Basin during the spring of 2008. Data was obtained for a total of 203 wells in 2008. The report contains data from these wells as well as other wells which are part of this monitoring effort, but for which data were not obtained in 2008. Historic data for all wells which are part of this monitoring effort are included in the report.

Most of the water level measurements in this year's report were obtained by Dave Dzurovchin, Michael Schaub and Elizabeth Pottoroff. Personnel from various water districts and municipalities also provided water level data for this report, including some data which were lacking from previous years. The Division of Water Resources requested water level information from some districts and municipalities that did not respond. The Division of Water Resources will continue to request this information on an annual basis, and appreciates the cooperation of the many entities that do provide water level information.

Included in this report is a summary of the Denver Basin geology with generalized aquifer maps and cross sections. The summary will also be included in future reports.

Copies of this report are made available to well owners and participating entities free of charge. Additional copies may be obtained from the Colorado Division of Water Resources, Public Records Section. The Records Section can be contacted at 1313 Sherman Street, Room 818, Denver CO 80203, or by phone at 303/866-3581 or 303/866-3447.

## **GEOLOGY OF THE DENVER BASIN AQUIFERS**

The Denver-Julesburg Basin is a structural sedimentary basin bounded by the Front Range on the west that extends northward into southern Wyoming. The administrative Denver Basin is a portion of the structural basin. The ground water resources administered for water rights within the basin extend east near Limon, Colorado, southward from near Greeley on the north to a location several miles to the south and east of Colorado Springs. In total, the administrative Denver Basin includes an area of more than 6,700 square miles. The basin is generally defined by the lower boundary of the Laramie-Fox Hills aquifer, which is the lowermost of the four principal aquifers found in the basin. Figure 1 is a map of the Denver Basin that identifies the lower boundary of each of the Denver Basin aquifers.

The formations present in the basin that comprise the principal aquifers are composed of sedimentary rocks that are up to 3,000 feet thick in the deepest part of the basin. A generalized cross-section is attached as Figure 2. In descending order, the hydrogeologic units are identified as the Dawson, Denver, Arapahoe, and Laramie-Fox Hills aquifers.

Extensive studies of these aquifers have been conducted over a period of about 100 years. Water from the aquifers has been utilized in the Denver area for domestic supplies since the 1880's. The most recent and most detailed study of the aquifer system was completed by the Colorado Division of Water Resources in 1985 as part of a legislatively mandated study commonly known as Senate Bill 5. During the study, the staff of the Division collected extensive information on the nature of the aquifers, the occurrence of ground water in the aquifers, and the effects of pumping ground water from the aquifers on surface streams throughout the basin. The estimated amount of water contained in the aquifers is presented in Table 1.

The Colorado Division of Water Resources' study resulted in re-defining the aquifer system into the four major aquifers currently recognized. For the reader to better understand the aquifer system, a brief discussion of each hydrogeologic unit is presented below. It should be noted that the Division's work in this area is recognized as the authoritative study of the Denver Basin aquifers, and is utilized by the consulting community and governmental/regulatory agencies.

### **DAWSON AQUIFER**

The Dawson aquifer is the uppermost aquifer in the basin and covers an area of approximately 1,400 square miles. The aquifer varies in thickness, depending upon location, and attains a maximum thickness of almost 1,200 feet in the vicinity of Monument. The Dawson is at or near the land surface throughout its entire areal extent. The aquifer is composed of predominately conglomeratic, coarse-grained arkosic sandstones with minor amounts of interbedded clay and clay shale. The northern portion of the aquifer can be subdivided into two

hydrogeologic units known as the Upper and Lower Dawson aquifers. This separation is based on the presence of an approximately 50-foot thick shale layer that hydraulically isolates the Upper and Lower Dawson aquifer units. The Dawson aquifer is separated from the underlying Denver aquifer by a clay shale sequence ranging from 25 to 50 feet thick.

## **DENVER AQUIFER**

The Denver aquifer consists of a series of interbedded clay shale, clay, claystone, siltstone and sandstone lenses. Carbonaceous material and coal beds are common within the hydrogeologic unit. The aquifer underlies an area of approximately 3,500 miles and varies in thickness from a feather edge up to 1,000 feet. Distinctive characteristics of the aquifer are the fine-grained nature of the material composing the aquifer and sandstone lenses of limited areal extent.

Although the aquifer is utilized extensively for domestic water supplies, relatively low well yields (generally 20 to 50 gallons per minute (gpm)) limit its use primarily to individual residential wells; however, a number of municipal wells have been developed with yields up to 100 gpm. The higher yield wells are not indicative of the aquifer's potential in most areas.

The Denver aquifer is separated from the underlying Arapahoe aquifer by an extensive clay shale unit approximately 50 feet thick. The clay shale interval serves as a hydraulic barrier between the aquifers.

## **ARAPAHOE AQUIFER**

The Arapahoe aquifer is composed of interbedded conglomerates, sandstones, siltstones, and clay shales. The aquifer underlies an area of almost 4,700 square miles and is generally about 400 feet thick. The northern portion of the hydrogeologic unit can be subdivided into an upper and lower aquifer that is separated by a shale sequence ranging from 50 to 100 feet thick.

High capacity wells (300+ gpm) are common in the Arapahoe and the aquifer is used extensively to supply municipal water systems. Water quality is generally good in the aquifer as evidenced by its use by Deep Rock Water to obtain water for bottling.

## **LARAMIE FORMATION**

The major part of the Laramie Formation forms the aquitard or hydraulic barrier that separates the Arapahoe aquifer from the underlying Laramie-Fox Hills aquifer. The formation consists of approximately 400 feet of clay shales with minor interbeds of sandstone and siltstone. Coal beds are common within the formation and have been mined commercially along the eastern margin of the basin. Minor amounts of water are present within the sandstones, but are rarely developed for water supplies. Water in the sandstone units is of generally poor quality due to the presence of sulfides and biogenic gas.

The basal portion of the Laramie Formation contains two relatively thick sandstone units (the A and B sandstones) which are hydraulically isolated from the upper part of the formation. These sandstone units, combined with the underlying Fox Hills Sandstone compose the hydrogeologic unit of the Laramie-Fox Hills aquifer.

### **LARAMIE-FOX HILLS AQUIFER**

The lowermost of the four Denver Basin aquifers is the Laramie-Fox Hills aquifer which underlies approximately 6,700 square miles and marks the areal extent of the basin for economic ground water development. The Laramie-Fox Hills aquifer is generally between 250 and 300 feet thick, which includes about 150 to 200 feet of fine-grained and medium-grained sandstone. The aquifer typically yields water in quantities sufficient for commercial development, and is extensively utilized throughout the basin. Well yields may be as high as 100 gpm, but are typically somewhat lower. Both the Laramie-Fox Hills and Arapahoe aquifers are generally under artesian pressure at the present time.

### **PIERRE SHALE**

The Pierre Shale underlies the Fox Hills Formation and is composed of up to 4,500 feet of clay shale with minor sandstone units. In general, there is not sufficient water in the intermittent sandstones for use in more than a single-family residence or possibly for the watering of livestock. This formation defines the boundary for development of ground water for commercial purposes in the Denver Basin.

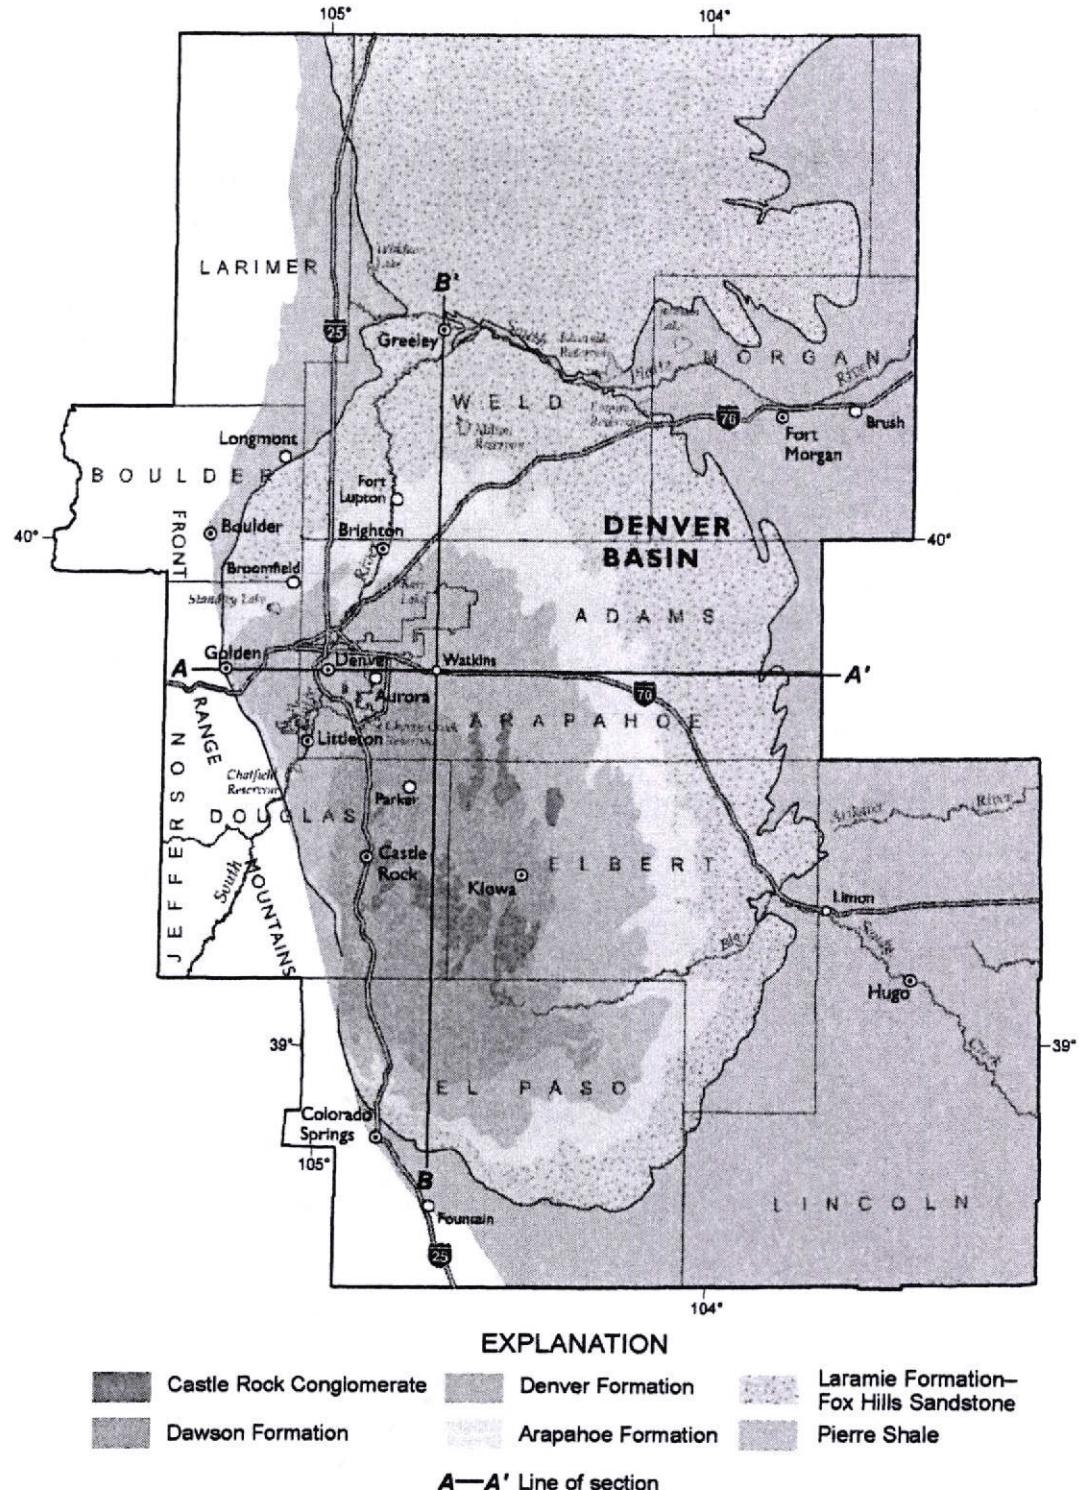

Figure 1. Extent of Denver Basin Aquifers, from Colorado Geological Survey Special Publication 53.

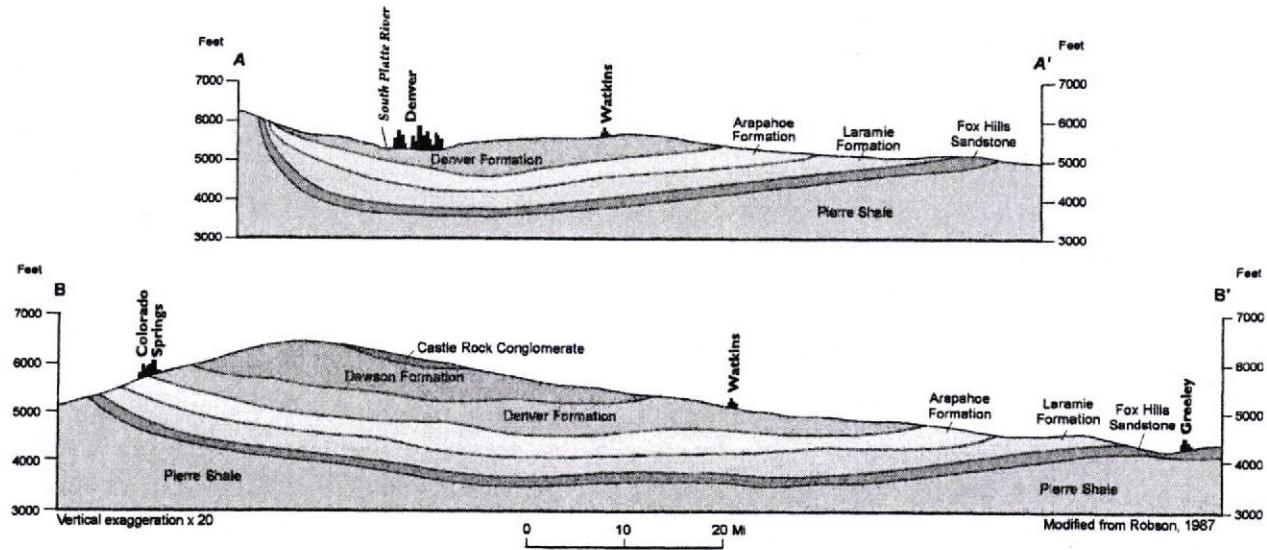

Figure 2. General cross section of Denver Basin Aquifers, from Colorado Geological Survey Special Publication 53.

### **GROUND WATER IN STORAGE**

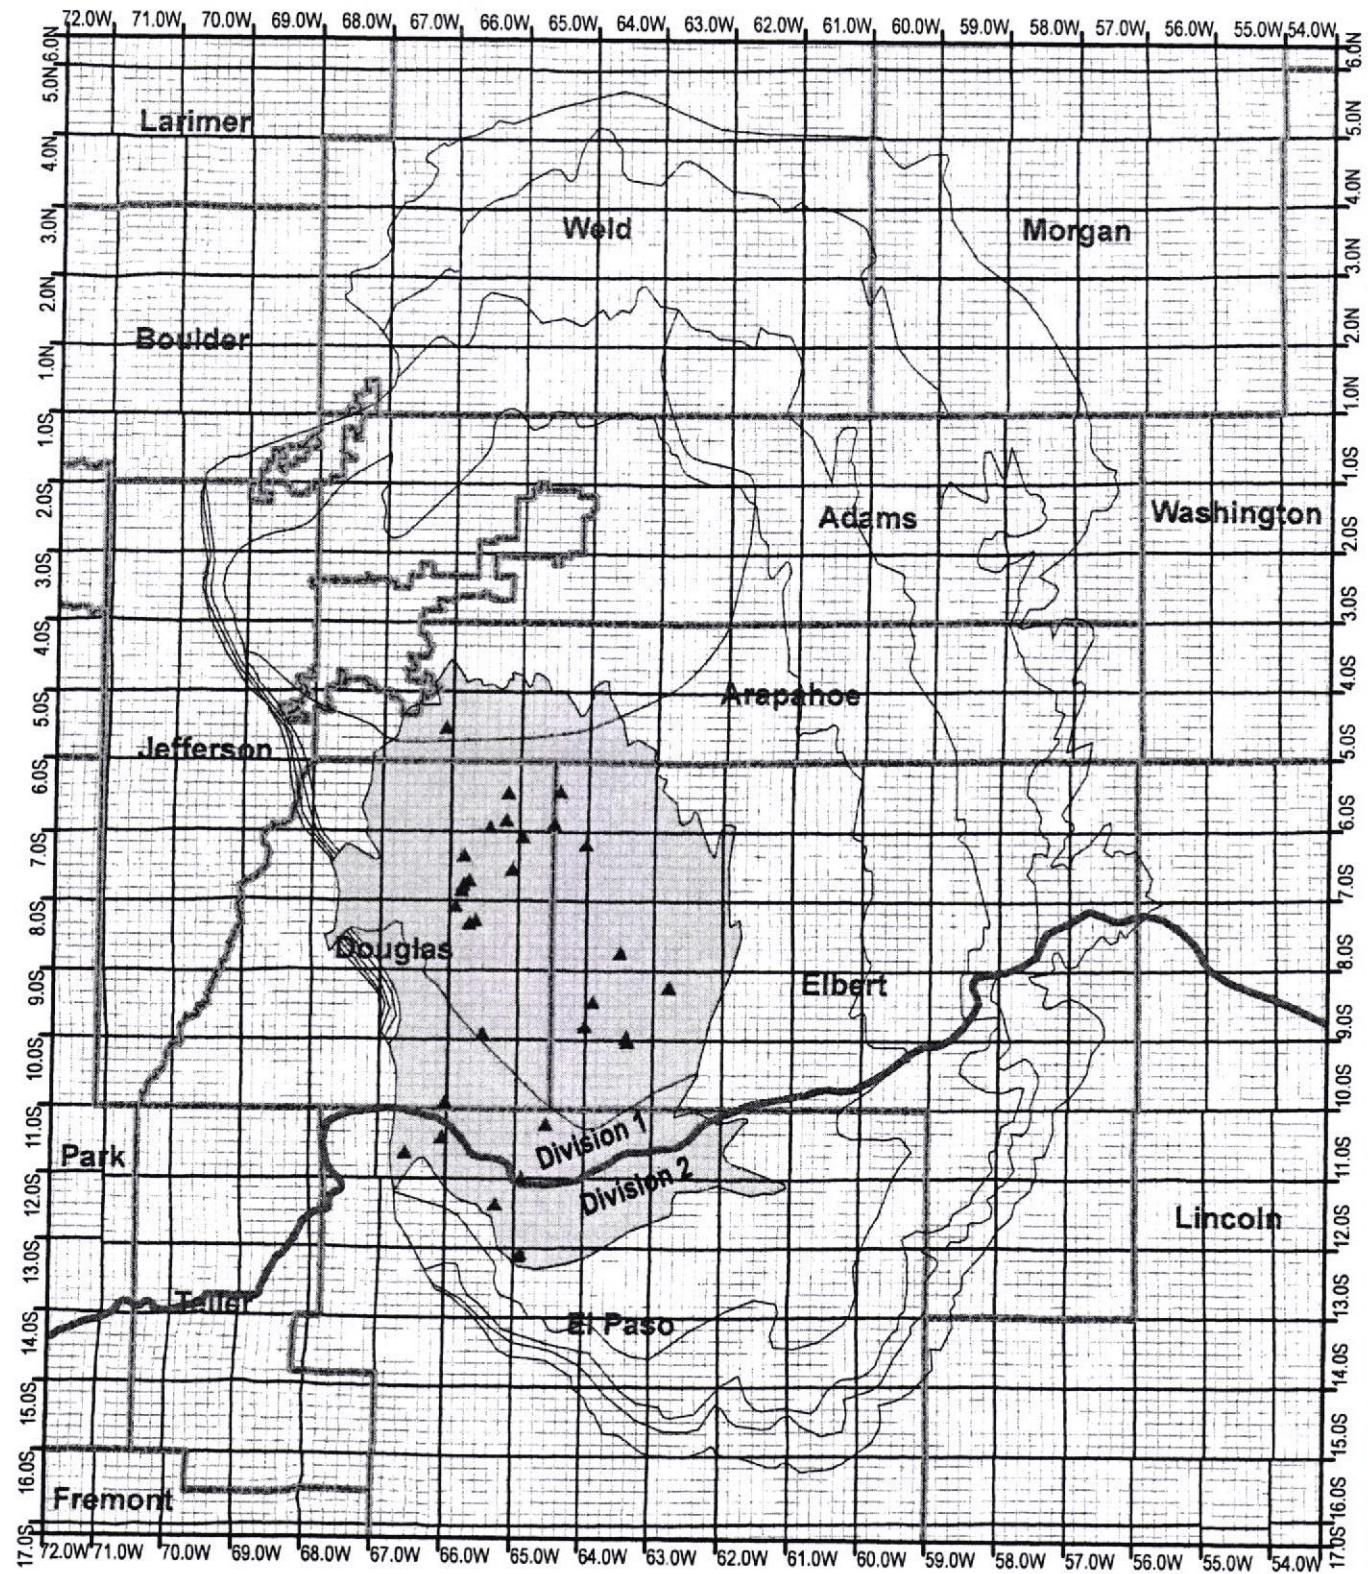

AQUIFER	SPECIFIC YIELD	VOLUME IN STORAGE (millions of acre-feet)
Upper Dawson	20	22
Lower Dawson	20	10
Denver	17	71
Upper Arapahoe	17	78
Lower Arapahoe	17	12
Laramie-Fox Hills	15	102
	TOTAL	295 million acre-feet

Note: Based on analysis of drill core from a location near Kiowa, the stated specific yield values may be as much as 25 to 30 percent above an "average" specific yield value for the Denver Basin aquifers. Therefore, the actual volume of water contained in the aquifers may be less than the volumes estimated.

Table 1: Estimated volume of water in storage in the Denver Basin aquifers.
